

Magneto-optical farady modulator

Overview

A magneto-optic spatial light modulator consists of one- or two-dimensional spatial array of independently addressable Faraday rotators placed between a polarizer and an analyzer. Light modulation is the process by which its properties, such as amplitude, phase, pulse width, and direction, are changed during passage through a medium. Two different schemes are employed for light modulation: internal modulation and external modulation. Internal modulation uses a simple circuit. The Faraday effect or Faraday rotation, sometimes referred to as the magneto-optic Faraday effect (MOFE), is a physical magneto-optical phenomenon. Polarization is rotated non-reciprocally, meaning that light. In Faraday Effect, the phase modulation of two mutually perpendicular components of linearly polarized light results into polarization modulation, which is then transformed into Amplitude Modulation by analyzer.

The Faraday effect or Faraday rotation, sometimes referred to as the magneto-optic Faraday effect (MOFE), is a physical magneto-optical phenomenon. The Faraday effect causes a polarization rotation which is proportional to the projection of the magnetic field along the direction of the light propagation. Formally, it is a special case of gyroelectromagnetism obtained when the dielectric permittivity tensor is diagonal. This effect occurs in most optically transparent dielectric materials (including liquids) under th
