

Optical power at the input of the optical receiver

AI Overview

The optical power of an incoming optical receiver is the received optical signal at the detector, which must meet or exceed the receiver's sensitivity to ensure correct data decoding.

Definition and Importance The received optical power refers to the actual optical signal arriving at the receiver after traveling through the fiber, accounting for all link losses such as fiber attenuation, connector losses, and splices. It is measured in dBm or mW and directly affects the bit error rate (BER) and overall signal quality. If the received power is too low, the receiver may fail to decode the signal correctly, leading to errors or link failure.

Receiver Sensitivity vs Minimum Receiver Power

Receiver Sensitivity: This is a specification of the optical receiver, representing the minimum optical power required to achieve a specified BER under ideal laboratory conditions. Lower (more negative) dBm values indicate better sensitivity, meaning the receiver can detect weaker signals.

Minimum Receiver Power: This is the actual received power at the receiver after considering all link losses and worst-case conditions, including temperature variations and aging components. It is used in link budget calculations to ensure the signal remains above the receiver sensitivity threshold. In practice, the minimum received power must be greater than or equal to the receiver sensitivity to maintain reliable communication. Exceeding the maximum receiver input power can also cause receiver overload, so both minimum and maximum limits are important.

Practical Considerations

Link Budgeting: Calculate total losses along the fiber link and ensure the received power meets the receiver sensitivity requirement. Include margins for aging, temperature, and other impairments.

Signal Quality: Adequate received power ensures a high signal-to-noise ratio (SNR), reducing BER and improving network reliability.

Receiver Input

There are basically three classes of optical receivers; resistive load input, high input impedance or integrating receivers and low input impedance. The resistive load input optical receiver is the

Optical Performance

Receiver sensitivity refers to the minimum input optical power required by the receiver to achieve a specified bit error rate (BER). A larger receiver sensitivity indicates poorer receiver performance.

Input Signal Optical Power

5. There is an optical preamplifier in an optical receiver before the photodiode. The input optical power to the optical amplifier is $P_{in} = -20$ dBm, and the optical amplifier has a 6-dB noise figure. Other
