

There are several types of optical cable laying

Overview

Optical fiber consists of a core and a cladding, selected for due to the difference in the refractive index between the two. In practical fibers, the cladding is usually coated with a layer of protective material. This coating protects the fiber from damage but does not contribute to its properties. Individual coated fibers (or fibers formed into ribbons or bundles) then have a protective jacket.

AI Overview

Optical cables can be laid using five main methods: direct burial, overhead (aerial), pipeline, underwater, and indoor installations, each suited to specific environments and requirements.

- 1. Direct Burial** Direct burial involves placing optical cables directly underground, typically at a depth of 0.8-1.2 meters depending on soil conditions. The process requires trenching, laying the cable at the trench bottom, and backfilling the soil. Protective measures, such as GYTA53 cable structures with steel strips and polyethylene sheaths, are often used to resist mechanical damage and soil corrosion. Marker stones are sometimes placed on the surface every 50 meters to facilitate maintenance. This method is widely used for long-distance trunk lines due to its reliability, though construction and maintenance costs are relatively high.
- 2. Overhead (Aerial) Installation** Overhead optical cables are suspended on utility poles and are suitable for areas where underground installation is difficult or costly. There are two main types:
 - Suspension wire type:** The cable is hung on a suspension wire attached to poles, with the wire bearing the load.
 - Self-supporting type:** The cable itself has a self-supporting wire integrated in an "8" shape, carrying its own weight.Overhead cables are more vulnerable to natural disasters, external forces, and mechanical stress, resulting in a higher failure rate compared to buried or ducted cables.
- 3. Pipeline Ins...**
