

What does an electro-optical module look like

Overview

An electro-optic modulator (EOM) is an optical device in which a signal-controlled element exhibiting an electro-optic effect is used to modulate a beam of light. The modulation may be imposed on the phase, frequency, amplitude, or polarization of the beam. Modulation bandwidths extending into the gigahertz range are possible with the use of laser-controlled modulators. The electro-optic phase modulation (PM) is a modulation pattern that encodes information as variations in the instantaneous phase of a carrier wave. The phase of a carrier signal is modulated to follow the message signal. A phase modulating EOM can also be used as an amplitude modulator by using a half-wave plate. This alternative technique is often used in applications where the requirements of phase stability are not as stringent. Depending on the type and orientation of the nonlinear crystal, and on the direction of the applied electric field, the phase delay can depend on the polarization direction. An EOM can thus be seen as a voltage-controlled device.
